

Tate Cycles on Abelian Varieties with Complex Multiplication

V. Kumar Murty and Vijay M. Patankar

Abstract. We consider Tate cycles on an Abelian variety A defined over a sufficiently large number field K and having complex multiplication. We show that there is an effective bound $C = C(A, K)$ so that to check whether a given cohomology class is a Tate class on A , it suffices to check the action of Frobenius elements at primes v of norm $\leq C$. We also show that for a set of primes v of K of density 1, the space of Tate cycles on the special fibre A_v of the Néron model of A is isomorphic to the space of Tate cycles on A itself.

1 Introduction and Statement of Results

Let K be a field that is finitely generated over its prime field. In our case, K will in fact be a number field or a finite field. Let A be an Abelian variety defined over K of dimension d , say. For a prime ℓ with $\ell \nmid \text{char}(K)$, and $n \geq 1$, we have the ℓ -adic Tate module

$$T_\ell(A) = \text{proj lim } A[\ell^n] \simeq \mathbb{Z}_\ell^{2d}.$$

In a natural way, it is a $G_K = \text{Gal}(\bar{K}/K)$ -module. Also set

$$V_\ell(A) = T_\ell(A) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell.$$

Set $\bar{A} = A \times_K \bar{K}$. Then, we may identify $V_\ell(A)$ with $H_{1,\ell}(\bar{A})$ and the cohomology of A with the exterior algebra on the dual of $V_\ell(A)$. As usual, for a G_K -module W , we denote by $W(k)$ the k -fold Tate twist of W .

For any field F with $K \subseteq F \subseteq \bar{K}$, set

$$\begin{aligned} \mathcal{T}_\ell^k(A, F) &= H_\ell^{2k}(\bar{A})(k)^{\text{Gal}(\bar{K}/F)}, \\ \mathcal{T}_\ell^*(A) &= \bigoplus_k \sum_{K \subseteq F \subseteq \bar{K}} \mathcal{T}_\ell^k(A, F). \end{aligned}$$

This is the space of Tate cycles on A . It is a finite dimensional \mathbb{Q}_ℓ vector space, and we may in fact restrict the field F above to be of finite degree over K . Thus, for some finite extension M of K , we have

$$\mathcal{T}_\ell^*(A) = \bigoplus_k H_\ell^{2k}(\bar{A})(k)^{\text{Gal}(\bar{K}/M)} = \bigoplus_k \mathcal{T}_\ell^k(A, M).$$

Again, for $K \subseteq F \subseteq \bar{K}$, let $Z^k(A, F)$ denote the free Abelian group generated by algebraic cycles of co-dimension k on A (modulo homological equivalence) with a

Keywords: abelian varieties, complex multiplication, Tate cycles.

representative defined over F . The ℓ -adic cycle class map is

$$c_{\ell,k,F}: Z^k(A, F) \otimes_{\mathbb{Z}} \mathbb{Q}_{\ell} \rightarrow \mathcal{T}_{\ell}^k(A, F).$$

Conjecture 1.1 ([16] Tate) *The ℓ -adic cycle class map is surjective.*

This was proved by Tate for $k = 1$ in the case K is a finite field and by Faltings in the case where K is a number field. This conjecture is not known to be independent of ℓ .

There is a related conjecture involving L -functions associated with A .

Conjecture 1.2 (Tate) *If K is a number field, $L(H_{\ell}^{2k}(\bar{A}), s)$ has a meromorphic continuation to $\text{Re}(s) = 1 + k$ and*

$$\text{ord}_{s=1+k} L(H_{\ell}^{2k}(\bar{A}), s) = -\dim \mathcal{T}_{\ell}^k(A, K).$$

If K is a finite field,

$$\text{ord}_{s=k} L(H_{\ell}^{2k}(\bar{A}), s) = -\dim \mathcal{T}_{\ell}^k(A, K).$$

Our aim is to study (in the case K is a number field) the relationship between $\mathcal{T}_{\ell}^*(A)$ and $\mathcal{T}_{\ell}^*(A_{\nu})$. Here ν is a prime of K of good reduction for A , ℓ is assumed to be distinct from the characteristic of the residue field k_{ν} (of K at ν), and A_{ν} stands for the reduction of A modulo ν .

At a prime ν of good reduction for A , we have the natural reduction map, $A \rightarrow A_{\nu}$, which induces a natural map (under pull-back) $H_{\ell}^*(A_{\nu}) \simeq H_{\ell}^*(\bar{A})$. Let

$$(1.1) \quad \iota_{\nu}: H_{\ell}^*(\bar{A}) \longrightarrow H_{\ell}^*(\bar{A}_{\nu})$$

be the inverse of this isomorphism. We may view both sides as $\mathbb{Q}_{\ell}[G_{\nu}]$ -modules, where $G_{\nu} \subset G_K$ is the decomposition group at ν (subgroup of G_K unique up to conjugation). Indeed, the left-hand side $H_{\ell}^*(\bar{A})$ is naturally a G_{ν} -module under restriction from G_K . The right-hand side is naturally a $\mathbb{Q}_{\ell}[G_{k_{\nu}}]$ module, where $G_{k_{\nu}}$ is the Galois group of the residue field k_{ν} at ν . Since $G_{k_{\nu}}$ is naturally a quotient of G_{ν} , we can consider $H_{\ell}^*(\bar{A}_{\nu})$ as a $\mathbb{Q}_{\ell}[G_{\nu}]$ -module. Also, as ν is a prime of good reduction, the criterion of Néron–Ogg–Shafarevich [13] implies that the inertia subgroup at ν acts trivially on $H_{\ell}^*(\bar{A})$. Thus, the two sides in (1.1) are isomorphic as $\mathbb{Q}_{\ell}[G_{\nu}]$ -modules, and so restriction gives us a map

$$(1.2) \quad \iota_{\nu}: \mathcal{T}_{\ell}^*(A) \rightarrow \mathcal{T}_{\ell}^*(A_{\nu}),$$

which is, in fact, injective.

We begin with the following observation. A class $\omega \in H_{\ell}^{2m}(\bar{A})(m)$ for which $\iota_{\nu}(\omega)$ is in $\mathcal{T}_{\ell}^m(A_{\nu}, k_{\nu})$ at almost all places ν of K (i.e., at all but finitely many places of K) is in $\mathcal{T}_{\ell}^m(A, K)$. Indeed, this follows from the Chebotarev density theorem. This observation can be strengthened as follows.

Proposition 1.3 *Let S be a set of places of K with positive Dirichlet density, say $\delta > 0$. A class $\omega \in H_{\ell}^{2m}(\bar{A})(m)$ for which $\iota_{\nu}(\omega)$ is in $\mathcal{T}_{\ell}^m(A_{\nu}, k_{\nu})$ at all places ν in S is in $\mathcal{T}_{\ell}^m(A)$.*

Proof Note that the ℓ -adic representation $\rho_\ell: G_K \rightarrow \text{Aut}(H_\ell^{2m}(\overline{A})(m))$ is unramified at all but finitely many places v of K . Let L be the sub-extension of \overline{K} fixed by $\text{Ker}(\rho_\ell)$. Then L is a Galois extension of K and is unramified at all except finitely many places of K . At a finite prime v , to be a Tate class means that it is fixed by the Frobenius automorphism in $\text{Gal}(\overline{k}_v/k_v)$ given by $x \mapsto x^{\mathbb{N}v}$, where $\mathbb{N}v$ is the cardinality of k_v (also the norm of v). The Frobenius automorphism lifts to Frob_v (at almost all v) and thus, by (1.1) as above and the assumption, ω is fixed by $\text{Frob}_v \in \text{Gal}(L/K)$. Let G_S be the group generated by $\{\text{Frob}_v \mid v \in S\}$ in $\text{Gal}(L/K)$ as a topological group. Let L^{G_S} be the sub-extension of L cut out by G_S . The places of S split completely in L^{G_S} . This implies that L^{G_S} is a finite extension of K . Moreover, by the Chebotarev density theorem, $[\text{Gal}(L/K):G_S] = [L^{G_S}:K] \leq 1/\delta$. Thus, it follows that if for all $v \in S$, $\iota_v(\omega)$ is in $\mathcal{T}_\ell^m(A_v, k_v)$, then ω is in $\mathcal{T}_\ell^m(A, L^{G_S})$, i.e., it is a Tate class. ■

With more work, we will show that in the case of Abelian varieties with complex multiplication, the condition of the above result can be replaced with a condition at a finite set of primes. Moreover, this can be done in an effective manner. Here also, the role of split primes is crucial.

We recall that for each prime ℓ , Serre and Tate [13] define a conductor of A (in terms of the Artin and the Swan character). It is an integer that they prove is independent of ℓ ([13, pp. 499–500]).

Theorem 1.4 *Let A be an Abelian variety with complex multiplication and let K be a number field over which both A and its endomorphisms are defined. Denote by d the dimension of A and by N the conductor of A . Then there is an effective bound $C = C(A, K)$ such that if $\omega \in H_{\ell_0}^{2m}(\overline{A})(m)$, for some prime ℓ_0 , is a Tate class considered as an element of $H_{\ell_0}^{2m}(\overline{A}_v)(m)$ for all v of K with $N_{K/\mathbb{Q}}v \leq C$, then ω is Tate, i.e., $\omega \in \mathcal{T}_{\ell_0}^m(A, K)$.*

Several remarks are in order.

Remark 1.5 The main point of the above theorem is that the bound C (defined by (6.2)) depends only on the Abelian variety A (in fact, only on the conductor, the dimension, and the discriminant of the field of complex multiplication) and the number field K and does not depend on ℓ_0 . However, if we fix a prime ℓ , it is possible to prove (using the Chebotarev density theorem and Nakayama’s lemma for finitely generated modules over \mathbb{Z}_ℓ) the existence of a constant (that would depend on A, K and ℓ) so that a similar statement as in the theorem above is true.

Remark 1.6 The proof of Theorem 1.4 will produce an explicit expression for C (as defined by (6.2)) only in terms of the degree n_K , the discriminant d_K of K , the conductor N , the dimension d of A and the discriminant d_F of the field F of multiplication of A . We have not made any effort to find an optimal bound. However, we note that with the assumption of the Riemann Hypothesis for Dedekind zeta functions, the estimate for C that comes from the proof of Theorem 1.4 can essentially be replaced by $(\log C)^2$. It would be very interesting to study to what extent it would be possible to get a bound that is uniform in each of the parameters n_K, d_K, N, d_F and d .

Remark 1.7 Tate [17, Section 3, pp. 76–77] discusses the notion of an “almost algebraic” cycle. A Tate cycle is said to be *almost algebraic* if all but finitely many of its specializations are algebraic. According to Tate, this notion seems to be part of the folklore. Tate adds: “it is mentioned explicitly in [11, 5.2] that Künneth components of the ‘diagonal’ are almost algebraic (by [1, Theorem 2(1)])”. Thus these “Künneth components of the diagonal” are examples of almost algebraic cycles that are not known to be algebraic. Tate further mentions a weaker conjecture than Conjecture 1.1: The space of Tate cycles is spanned by almost algebraic cycles.

Remark 1.8 Let us assume the Tate conjecture for Abelian varieties over finite fields. Suppose that ω is a class in $H_\ell^{2m}(\bar{A})(m)$ with the property that $\iota_v(\omega)$ is algebraic for each prime v of K of norm $\leq C$. Then $\iota_v(\omega)$ is algebraic for all but finitely many v . Indeed, by the above Theorem, ω is a Tate class, and hence so is its reduction $\iota_v(\omega)$. Now, by our assumption, it follows that $\iota_v(\omega)$ is algebraic. Hence ω is almost algebraic.

Our next result is about the field of definition of Tate cycles on an Abelian variety over a finite field obtained by reduction of Tate cycle on a fixed Abelian variety over a number field.

Theorem 1.9 *Let A be an Abelian variety defined over a number field K . Then there is a bound $D = D(A)$ so that for all v of good reduction, all Tate cycles on A_v are defined over an extension of the residue field k_v of degree $\leq D$.*

Remark 1.10 In fact our proof of this theorem can be suitably adapted to show that all the Tate cycles on an Abelian variety A over a number field K with complex multiplication by F are defined over a “specific” extension of K that depends on $d = \dim(A)$, the conductor of A , and the normal closure of F .

As is well known (and as implied by (1.2)) the dimension of the space of Tate cycles does not decrease under reduction modulo v . Our next result shows that in the CM case, for a set of primes of Dirichlet density 1, it does not increase either. The proof of this theorem uses Theorem 1.9.

Theorem 1.11 *Let A be an Abelian variety of CM type. Let K be sufficiently large so that all the Tate cycles on A and all the endomorphisms of A are defined over K . Then, for a set of primes v of K of Dirichlet density 1,*

$$\mathcal{T}_\ell^*(A) \simeq \mathcal{T}_\ell^*(A_v).$$

In particular, the Tate conjecture for A implies the Tate conjecture for A_v for a set of primes v of Dirichlet density 1.

Remark 1.12 The condition that K be sufficiently large is necessary as the following example illustrates. Let E be an elliptic curve over \mathbb{Q} with complex multiplication by an imaginary quadratic field, say $K = \mathbb{Q}(\sqrt{-d})$, with d a square-free and positive integer. Let $A = E \times E$. Then $Z^1(A, K)$ is generated by $E \times \{0\}$, $\{0\} \times E$, the diagonal

$\Delta := \{(x, x) | x \in E\}$, and the graph of complex multiplication

$$\Delta' := \{(x, [\sqrt{-d}]x) | x \in E\},$$

where $[\sqrt{-d}]$ denotes the endomorphism of E whose square is $[-d]$.

Then E has super-singular reduction at a prime p of \mathbb{Q} that remains inert in K and of good reduction for E . Let A_p denote the reduction of A modulo p over \mathbb{F}_p . Then, $Z^1(A_p, \overline{\mathbb{F}_p})$ is generated by $E_p \times \{0\}$, $\{0\} \times E_p$, Δ_p (the reduction of Δ modulo p), Δ'_p (the reduction of Δ' modulo p), $\Delta_\phi := \{(x, \phi(x)) | x \in E_p\}$, and $\Delta_\psi := \{(x, \psi(x)) | x \in E_p\}$, where ϕ and ψ are the other two generators of $\text{End}_{\overline{\mathbb{F}_p}}(E_p)$. This proves that for such primes p , the rank of $\mathcal{T}_\ell^1(A)$ is 4 and the rank of $\mathcal{T}_\ell^1(A_p)$ is 6. Thus, the *reduction* map as in (1.2) is strictly injective for a set of primes p of \mathbb{Q} of Dirichlet density $\frac{1}{2}$! However, this is not a problem, as the set of primes of \mathbb{Q} that are inert in K , has Dirichlet density 0 considered as a set of primes of K .

Remark 1.13 The theorem is not true for Abelian varieties without complex multiplication as the following example illustrates. Let E be an elliptic curve over \mathbb{Q} without complex multiplication. Let $A = E \times E$ be as above. Then $Z^1(A, K)$ is generated by $E \times \{0\}$, $\{0\} \times E$ and the diagonal Δ for any number field K . Let v be a finite place of K of good reduction for E and let k_v be the finite residue field at v . Then E always acquires the extra endomorphism (the *Frobenius*) and $Z^1(A_v, k_v)$ has rank at least 4. Thus, $\mathcal{T}_\ell(A)$ strictly injects into $\mathcal{T}_\ell(A_v)$ for all but finitely many places of K .

Remark 1.14 In our previous work [7], we studied the problem of when A_v stays simple for a set of primes of positive density, given that A is simple (or absolutely simple). If A_v splits, this gives rise to extra classes in the Néron–Severi group of A_v (and hence also extra Tate cycles on A_v).

In Section 2, we recall some basic properties of a compatible family of λ -adic representations. In Section 3, we recall some basic properties of the theory of complex multiplication. In Section 4, we develop an analytic estimate that will be crucial in the proofs of our main results. In Section 5, we present the Main Lemma, and in the following three sections, we give the proofs of Theorems 1.4, 1.9, and 1.11.

2 Brief Background on Compatible Family of λ -adic Representations

We recall (from [10]) some basics about *compatible* families of λ -adic Galois representations.

Let K be a number field. Let \overline{K} be a separable algebraic closure of K . Let G_K denote the Galois group of \overline{K} over K . Let E_λ be a non-archimedean local field (finite extension of some p -adic field). Let V be a vector space over E_λ . Let $\text{Aut}(V)$ be the general linear group of V with topology induced by that on $\text{End}(V)$. If $n = \dim(V)$, we have $\text{Aut}(V) \simeq \text{GL}(n, E_\lambda)$.

Definition 2.1 A λ -adic representation of G_K (or of K) is a continuous homomorphism $\rho: G_K \rightarrow \text{Aut}(V)$, where V is vector space over a non-archimedean local field E_λ , a finite extension of \mathbb{Q}_p .

For any number field F , we denote by Σ_F the set of finite places of F . Recall that a λ -adic representation ρ is said to be *rational* (resp., *integral*) if there exists a finite subset S of Σ_K such that

- (a) for any place v in $\Sigma_K - S$, ρ is unramified at v ;
- (b) for $v \notin S$, the coefficients of $P_{v,\rho}(T)$ belong to \mathbb{Q} (resp., \mathbb{Z}).

Let E be a number field. For each finite prime λ of E , let ρ_λ be a rational λ -adic representation of K . For any given finite prime λ of E , let us denote by ℓ_λ the prime of \mathbb{Q} that lies below the prime λ of E . The system $\{\rho_\lambda\}$ is said to be *strictly compatible* if there exists a finite subset S of Σ_K , called the *exceptional set*, such that:

- (a) for $S_\lambda := \{v|v \text{ lies over } \ell_\lambda\}$ and every $v \notin S \cup S_\lambda$, ρ_λ is unramified at v and $P_{v,\rho_\lambda}(T)$ has rational integral coefficients;
- (b) $P_{v,\rho_\lambda}(T) = P_{v,\rho_{\lambda'}}(T)$ if $v \notin S \cup S_\lambda \cup S_{\lambda'}$.

Definition 2.2 Let $\rho(= \rho_\lambda)$ be a λ -adic representation of G_K . Then we say that ρ is pure of weight $w \in \mathbb{Z}$ if there is a finite set S of finite places of K such that, for each finite place $v \notin S \cup S_\lambda$, $\rho(\text{Frob}_v)$ is unramified, and the eigenvalues of $\rho(\text{Frob}_v)$ are algebraic integers whose complex conjugates have complex absolute value $q_v^{w/2}$, where q_v is the cardinality of the residue field of K at v . We say that a compatible family $\{\rho_\lambda\}$ is of weight $w \in \mathbb{Z}$ if for each finite place λ of E , ρ_λ is of pure weight w .

As usual, we denote by χ_ℓ the cyclotomic character giving the action of $\text{Gal}(\overline{K}/K)$ on ℓ -power roots of unity. The $\{\chi_\ell\}$ form a compatible family of ℓ -adic representations.

3 Abelian Varieties with Complex Multiplication and the Shimura–Taniyama Theorem

We now briefly recall a few basic facts about Abelian varieties of *Complex Multiplication* (CM) type. The main references are [3, 8, 13, 14].

Let A be an Abelian variety defined over a number field K of dimension $d := \dim(A)$. Let F be a number field of degree $2d$. Then A is said to have CM by F if there exists an embedding

$$\iota: F \rightarrow \text{End}_{\mathbb{Q}}(A) := \text{End}_{\overline{\mathbb{Q}}}(A) \otimes_{\mathbb{Z}} \mathbb{Q}.$$

It is a fact that such an F must be a totally imaginary extension of a totally real number field. Let E be the Galois closure of F . To such an Abelian variety, the Shimura–Taniyama theory associates Hecke characters $\psi_{i,\lambda}$ of the following type. For each $1 \leq i \leq 2d$ and for each finite place λ of E (lying over a prime ℓ), we have a family of continuous characters of the Galois group $G_K := \text{Gal}(\overline{K}/K)$:

$$\psi_{i,\lambda}: G_K \rightarrow E_\lambda^\times$$

with the property that for all v not dividing ℓN , $\psi_{i,\lambda}(\text{Frob}_v) \in F^\times$. Thus, the field generated by $\psi_{i,\lambda}(\text{Frob}_v)$ for all v over \mathbb{Q} is contained in E . We have the following well-known result ([8, Theorem 2', p. 171]):

Theorem 3.1 (Shimura–Taniyama) (With notations and definitions as above) Let A be an Abelian variety defined over a number field with CM F . Let $H_\ell^k(\bar{A})$ be the k -th ℓ -adic étale cohomology of A . Then

$$H_\ell^k(\bar{A}) \otimes_{\mathbb{Q}_\ell} \overline{\mathbb{Q}_\ell} = \wedge^k H_\ell^1(\bar{A}) \otimes_{\mathbb{Q}_\ell} \overline{\mathbb{Q}_\ell} = \oplus_I H_I,$$

where the direct sum is over subsets $I \subseteq \{\psi_{1,\lambda}, \dots, \psi_{2d,\lambda}\}$ of cardinality k and where each H_I is a one dimensional G_K invariant $\overline{\mathbb{Q}_\ell}$ subspace of $H_\ell^k(\bar{A}) \otimes_{\mathbb{Q}_\ell} \overline{\mathbb{Q}_\ell}$. Further more, for any finite place v of K away from ℓ and from places of bad reduction for A , and for all $x \in H_I$

$$(\text{Frob}_v)^{-1}(x) = \left(\prod_{\psi_{i,\lambda} \in I} \psi_{i,\lambda}(\text{Frob}_v) \right) \cdot x.$$

In fact, the Shimura–Taniyama theory implies that for $1 \leq i \leq 2d$, $(\psi_{i,\lambda})_\lambda$ forms a compatible family of 1-dimensional continuous λ -adic representations of G_K , where λ runs over finite places of E . We denote these compatible families by ψ_i . Let $\Psi := \{\psi_1, \dots, \psi_{2d}\}$ and $\Psi_\lambda := \{\psi_{1,\lambda}, \dots, \psi_{2d,\lambda}\}$.

Theorem 3.2 (With notations as above) Let λ be a prime of E lying over ℓ . Then

$$H_\ell^{2k}(\bar{A}) \otimes_{\mathbb{Q}_\ell} E_\lambda = \oplus_I H_{I,\lambda}$$

where $I \subseteq \Psi_\lambda$ of size $2k$ and $H_{I,\lambda}$ is a 1 dimensional G_K invariant E_λ -subspace such that for any finite place v of K away from ℓ and places of bad reduction for A ,

$$(\text{Frob}_v)^{-1}(x) = \left(\prod_{\psi_{i,\lambda} \in I} \psi_{i,\lambda}(\text{Frob}_v) \right) \cdot x$$

for $x \in H_{I,\lambda}$.

We have the following corollary.

Corollary 3.3 With notations and definitions as above, $\{H_{I,\lambda}\}$ is a strictly-compatible family of λ -adic representations of G_K as λ varies over finite places of E .

4 The Least Prime That Does Not Split Completely

Let L and K be number fields with $K \subseteq L$. In the proof of our results, it will be necessary to have an estimate for the norm of a prime v of K that does not split completely in L . Such an estimate is given in [6, Theorem 1], assuming the Generalized Riemann Hypothesis for the Dedekind zeta function $\zeta_L(s)$ of s and assuming that L/K is Galois. In the case that $K = \mathbb{Q}$, an unconditional estimate is given by X. Li in [4, Theorem 1], and also by Vaaler and Voloch in [18]. However, we need an (unconditional) estimate for a general K . Such an estimate is remarked after the proof of [6, Theorem 1]. What we prove is slightly weaker, though more than sufficient for our purposes.

Let us denote by n_L and n_K the degrees of L and K over \mathbb{Q} respectively. Let d_L and d_K denote the discriminants of L/\mathbb{Q} and K/\mathbb{Q} , respectively. We also note the effective prime number theorem in K as given by Lagarias and Odlyzko (see [2] and

[12, Théorème 2]). This theorem tells us that the number $\pi_K(x)$ of primes of K of norm $\leq x$ satisfies

$$(4.1) \quad |\pi_K(x) - \text{Li } x + \text{Li}(x^\beta)| \leq c_1 x \exp(-c_2 \sqrt{\log x/n_K})$$

provided $x \geq c_3 n_K (\log |d_K|)^2$. Here, $c_1, c_2, c_3 > 0$ are absolute and effective constants and β is the possible exceptional zero of the Dedekind zeta function $\zeta_K(s)$. If it exists, it is real and satisfies

$$1 - \frac{1}{4 \log |d_K|} < \beta < 1.$$

Let us set

$$(4.2) \quad f(K) = \begin{cases} n_K^2 & \text{if } \zeta_K(s) \text{ does not have} \\ \max(n_K! \log |d_K|, |d_K|^{1/n_K}) + n_K^2 & \text{an exceptional zero,} \\ & \text{otherwise.} \end{cases}$$

Thus, for example, $f(\mathbb{Q}) = 1$.

Theorem 4.1 *There is an effective and absolute constant $c > 0$ with the following property. Let K be a number field and let L/K be a finite non-trivial Galois extension of degree n . Then, there exists a prime ideal \wp of K such that*

- \wp is of degree 1 over \mathbb{Q} and unramified in L ;
- \wp does not split completely in L , and

$$\mathbb{N}_{K/\mathbb{Q}} \wp < \max(55, e^{cf(K)} |d_L|^{4/(n-1)}).$$

Proof From [15, Lemma 3], we have for $\sigma > 1$, the inequality

$$(4.3) \quad -\frac{\zeta'_L}{\zeta_L}(\sigma) < \frac{1}{\sigma} + \frac{1}{\sigma - 1} + \frac{1}{2} \log \left(\frac{|d_L|}{2^{2r_2} \pi^{n_L}} \right) + \frac{r_1}{2} \frac{\Gamma'}{\Gamma}(\sigma/2) + r_2 \frac{\Gamma'}{\Gamma}(\sigma).$$

On the other hand, we have the Dirichlet series expansion

$$-\frac{\zeta'_L}{\zeta_L}(\sigma) = \sum_{\mathfrak{p}, m} \frac{\log \mathbb{N} \mathfrak{p}}{(\mathbb{N} \mathfrak{p})^{m\sigma}},$$

where the sum ranges over primes \mathfrak{p} of L and $1 \leq m \in \mathbb{Z}$. If all primes \wp of K that are of degree 1 over \mathbb{Q} and of norm less than y (say) ramify or split completely in L , then we see that with $n = [L:K] = n_L/n_K$,

$$-\frac{\zeta'_L}{\zeta_L}(\sigma) \geq n \sum_{\substack{\wp \\ \mathbb{N} \wp \leq y}} \frac{\log \mathbb{N} \wp}{(\mathbb{N} \wp)^\sigma},$$

where the prime on the summation indicates that we range over primes \wp of K that are of degree 1 over \mathbb{Q} and are unramified over L . Thus,

$$-\frac{\zeta'_L}{\zeta_L}(\sigma) \geq n \sum_{\mathbb{N} \wp \leq y} \frac{\log \mathbb{N} \wp}{(\mathbb{N} \wp)^\sigma} - nS_1 - nS_2,$$

where

$$S_1 = \sum_{\mathbb{N} \wp \leq y} \frac{\log \mathbb{N} \wp}{(\mathbb{N} \wp)^\sigma},$$

and the sum is taken over primes \wp of K that ramify in L , and

$$S_2 = \sum_{\substack{N_\wp \leq y \\ \wp \text{ of degree } \geq 2}} \frac{\log N_\wp}{(N_\wp)^\sigma}.$$

For each prime \wp counted in this sum, let p be the rational prime that it divides. Then $(\log N_\wp)/(N_\wp)^\sigma \leq 2(\log p)/p^{2\sigma}$. Moreover, given a rational prime p , there are at most n_K primes \wp of K dividing p , and so

$$S_2 \leq 2n_K \sum_p \frac{\log p}{p^{2\sigma}} \leq 2n_K.$$

We are using the fact that for the Riemann zeta function, the inequality (4.3) gives

$$\sum_p \frac{\log p}{p^{2\sigma}} < -\frac{\zeta'}{\zeta}(2\sigma) < 1$$

for $\sigma > 1$. For S_1 , we have ([6, p. 558])

$$S_1 \leq \sum_{\wp | d_{L/K}} \log N_\wp \leq \frac{2}{n} \log d_L.$$

Thus,

$$(4.4) \quad -\frac{\zeta'_L}{\zeta_L}(\sigma) \geq n \sum_{N_\wp \leq y} \frac{\log N_\wp}{(N_\wp)^\sigma} - 2 \log d_L - 2n_L.$$

To estimate the sum on the right, we use (4.1). Let us assume that $y \geq y_0 = c_3 n_K (\log |d_K|)^2$. By partial summation, we have

$$(4.5) \quad \sum_{N_\wp \leq y} \frac{\log N_\wp}{(N_\wp)^\sigma} = \pi_K(y)(\log y)y^{-\sigma} + \int_1^y \pi_K(t)t^{-1-\sigma}(\sigma \log t + 1)dt.$$

The first term on the right is bounded by using the estimate $\pi_K(x) \leq n_K \pi(x)$. Thus, we see that as $\sigma > 1$,

$$\pi_K(y)(\log y)y^{-\sigma} \leq c_4 n_K.$$

Similarly, we see that

$$\int_1^{y_0} \pi_K(t)t^{-1-\sigma}(\sigma \log t + 1)dt \leq 2c_4 n_K \log y_0.$$

The estimate (4.1) implies that replacing $\pi_K(t)$ with $\text{Li}(x) - \text{Li}(x^\beta)$ in the integral in (4.5) results in an error of at most

$$\leq 2 \int_1^{\log y} \exp(-c_1 \sqrt{u/n_K}) u du \leq c_5 n_K^2.$$

The term coming from the possible exceptional zero contributes to the integral an amount that is easily seen to be

$$\ll (\sigma - \beta)^{-1} < (1 - \beta)^{-1}.$$

To estimate this, we note that by [15, equations (27) and (28)], we have

$$\beta < \max(1 - (4n_K! \log |d_K|)^{-1}, 1 - (c_6 |d_K|^{1/n_K})^{-1}).$$

This implies that

$$(1 - \beta)^{-1} < \max(4n_K! \log |d_K|, c_6 |d_K|^{1/n_K}).$$

Let us denote the right-hand side by c_K . Finally, it remains to estimate

$$\int_{y_0}^y (\text{Li } t) t^{-1-\sigma} (\sigma \log t + 1) dt.$$

and this is easily seen to be

$$\sigma \int_1^y t^{-\sigma} dt + O\left(\int_1^y t^{-\sigma} (\log t)^{-1} dt\right).$$

Taking $\sigma = 1 + (\log y)^{-1}$, this is easily seen to be $\geq (1 - e^{-1}) \log y - c_7 \log \log y$. Putting all this together into (4.4), we deduce that

$$\begin{aligned} -\frac{\zeta'_L}{\zeta_L}(\sigma) &\geq n(1 - e^{-1}) \log y - n(c_K + c_5(\log |d_K|)^2 + c_7 \log \log y) \\ &\quad - c_8 n_L \log y_0 - 2 \log d_L - 2n_L. \end{aligned}$$

On the other hand, we can combine this with the upper bound given above (4.3). As mentioned in [15, p. 142], we have $\Gamma'(\sigma/2) < 0$ and $\Gamma'(\sigma) < 0$ for $1 < \sigma < 5/4$. Moreover, $\Gamma(x) > 0$ for $x > 0$ real. Hence, we deduce that provided $y > e^4 \sim 54.6$, there is an absolute and effective constant $c_9 > 0$ such that

$$n(1 - e^{-1}) \log y < 1 + \log y + \frac{5}{2} \log |d_L| + c_9 n f(K)$$

with $f(K)$ given by (4.2). It follows that there is a $c > 0$ such that

$$\log y \leq c f(K) + \frac{4}{(n-1)} \log |d_L|.$$

Thus, if $y > e^{cf(K)} |d_L|^{4/(n-1)}$, we get a contradiction, and this proves the result. ■

We record here the following estimate of Hensel (see, for example, [5, pp. 44–45]), which we shall also need. We have

$$\log d_L \leq (n_L - 1) \sum_{p \in P(L/\mathbb{Q})} \log p + n_L (\log n_L) |P(L/\mathbb{Q})|,$$

where $P(L/\mathbb{Q})$ is the set of rational primes p that ramify in L . In fact, when L is Galois over K , the following stronger estimate holds:

$$\log d_L \leq (n_L - n_K) \sum_{p \in P(L/K)} \log p + n_L (\log n_L - \log n_K) + \frac{n_L}{n_K} \log d_K.$$

In particular, if L/K is a Galois extension unramified outside of primes dividing M , then

$$(4.6) \quad \log d_L \ll n_L \log \left(M \frac{n_L}{n_K} \right) + \frac{n_L}{n_K} \log d_K.$$

5 Proof of the Main Lemma

Lemma 5.1 Suppose $\omega \in H_1^*(\bar{A})$ is a (simultaneous) eigenvector for a conjugacy set $C \subset G_K$. Then so is every element of $\mathbb{Q}_\ell[G_K](\omega)$, the G_K -module generated by ω inside $H_1^*(\bar{A})$.

Proof We need to show that for any $g \in G_K$, $g(\omega)$ is an eigenvector for any $\sigma \in C$. We have

$$\begin{aligned} \sigma(g(\omega)) &= g((g^{-1}\sigma g)(\omega)) \\ &= g(\tau(\omega)), && \text{for some } \tau \in C \text{ as } C \text{ is a conjugacy set} \\ &= g(\lambda_\tau \cdot \omega) && \text{for some } \lambda_\tau \in \mathbb{Q}_\ell \text{ by assumption} \\ &= \lambda_\tau \cdot g(\omega). \end{aligned}$$

The last step follows from the \mathbb{Q}_ℓ linearity of the G_K action. ■
 For integers $N, m, d \geq 1$ and a number field K , let us set

$$B = B(N, K, m, d) = e^{f(K)} N^{mn_K d^2} (f(K) + n_K \log N)^{mn_K d^2 + 1}.$$

Here

$$f(K) = \begin{cases} n_K^2 & \text{if } \zeta_K(s) \text{ does not have} \\ \max(n_K! \log |d_K|, |d_K|^{1/n_K}) + n_K^2 & \text{an exceptional zero,} \\ & \text{otherwise.} \end{cases}$$

as defined by (4.2), and $n_K = [K:\mathbb{Q}]$.

Let G_K denote the absolute Galois group of a number field K . Let E be some number field and \mathcal{O}_E the ring of integers of E . For a finite place λ of E , we denote by E_λ the completion of E at λ , and by \mathcal{O}_λ the ring of integers of E_λ . Let $\{M_\lambda\}$ be a family of continuous $\mathcal{O}_\lambda[G_K]$ -modules such that $\{M_\lambda \otimes_{\mathcal{O}_\lambda} E_\lambda\}$ is a strictly compatible family of continuous semi-simple λ -adic integral representations of G_K of weight $2w$, conductor N and dimension d , where λ varies over all finite places of E . Let S' be the set of exceptional places of K for the system $\{M_\lambda\}$.

Lemma 5.2 (Main Lemma) There are absolute and effective constants $c_1, c > 1$ so that if for some finite place λ_0 of E , the set

$$S = \{\text{Frob}_v : \mathbb{N}v \leq c_1 B(Nwd^2 \log d_E, K, n_E, d)^c\}$$

acts as scalars on M_{λ_0} , then G_K acts as scalars on M_λ and hence on any M_λ where λ is a finite place of E .

Proof By abuse of notation, we will use M_λ to denote M_λ as a module over \mathcal{O}_E and as well as the associated vector space $M_\lambda \otimes_{\mathcal{O}_E} E_\lambda$ over E_λ .

First suppose that Frob_v acts as a scalar μ on M_λ . Then $(\mathbb{N}v)^{wd} = \mu^d$, since the characteristic polynomial of Frob_v has coefficients in \mathbb{Z} . So, in fact, $\mu = \epsilon(\mathbb{N}v)^w$ with $\epsilon^d = 1$. Since $\{\rho_\lambda\}$ is a compatible family of rational integral representations, the trace $d\epsilon(\mathbb{N}v)^w$ of Frob_v , lies in \mathbb{Z} and so $\epsilon = \pm 1$.

If $d = 1$, then there is nothing to prove, so we may assume without loss of generality that $d > 1$. Suppose that G_K does not act as scalars on M_{λ_0} . By compatibility,

G_K does not act as scalars on the family $\{M_\lambda\}$. We shall show that S does not act as scalars either.

Let S' be the exceptional set (of places of K) for the system $\{M_\lambda\}$. For a finite place λ of E , let ℓ_λ denote the prime of \mathbb{Q} that lies below λ . Let $S_\lambda := \{v \mid v \text{ lies over } \ell_\lambda\}$, the set of finite places of K that divide ℓ_λ . For $v \notin S' \cup S_\lambda$, let

$$P_{v,\lambda}(T) := \det(T - \rho_\lambda(\text{Frob}_v)).$$

By compatibility, $P_{v,\lambda}(T)$ is independent of λ .

Let $v \notin S'$ be the prime with least norm such that Frob_v does not act as a scalar on M_{λ_0} . (Note that Frob_v is unique up to conjugation.) Since ρ_λ is a semi-simple representation, this is equivalent to $P_v(T) \neq (T - \theta_v)^d$ for any $\theta_v \in \mathbb{C}$. Thus by compatibility, Frob_v does not act as a scalar on M_λ for any λ .

Denote the eigenvalues of Frob_v by $\{\alpha_{i,v}\}$ for $i = 1$ to d . Let us choose ℓ unramified in E so that the distinct eigenvalues of Frob_v remain distinct modulo ℓ . This can be done by choosing an ℓ that does not divide the discriminant of E and the norm of the product of the differences of any two distinct eigenvalues of Frob_v . We have

$$|\prod(\alpha_{i,v} - \alpha_{j,v})| \leq (2(\mathbb{N}v)^w)^{d^2},$$

where the product is over pairs of distinct eigenvalues of Frob_v . Thus, we can find such an ℓ satisfying

$$(5.1) \quad \ell \ll \log\{d_E(2(\mathbb{N}v)^w)^{d^2}\} \ll wd^2 \log \mathbb{N}v + \log d_E,$$

where the implied constant is absolute.

Here, we are using the fact that for an integer $m > 1$, there exists a prime that is $O(\log m)$ that does not divide m . Indeed, by the prime number theorem, the product of all the primes less than $3 \log m$ (say) would be larger than m . Hence, at least one of these primes does not divide m .

It then follows that for at least one of the places λ of E that lie over ℓ , the distinct eigenvalues of Frob_v remain distinct modulo λ . Thus, Frob_v does not act as a scalar on $\overline{M_\lambda} = M_\lambda/\lambda M_\lambda$.

Let $\overline{\rho_\lambda}$ be the natural map from G_K to $PGL(\overline{M_\lambda})$, the projective general linear group associated with $\overline{M_\lambda}$. By above, the image of Frob_v to $PGL(\overline{M_\lambda})$ is not the identity. By applying Theorem 4.1 to this representation, it follows that there exists a prime v' (say) for which the image of $\text{Frob}_{v'}$ in $PGL(\overline{M_\lambda})$ is not the identity. In particular, v' does not split completely in the fixed field L (say) of the kernel of $\overline{\rho_\lambda}$. We know that L is unramified outside ℓN , and as

$$\log \frac{n_L}{n_K} \leq [E:\mathbb{Q}]d^2 \log \ell,$$

it follows by (4.6) that

$$\log d_L \ll n_L[E:\mathbb{Q}]d^2 \log N\ell + \frac{n_L}{n_K} \log d_K.$$

Then by Theorem 4.1 and $n = n_L/n_K \geq 2$, we can choose v' satisfying

$$\log Nv' \ll f(K) + \frac{n_K}{n_L} \log d_L \ll f(K) + n_K[E:\mathbb{Q}]d^2 \log N\ell.$$

By (5.1), we have

$$\log N\nu' \ll f(K) + n_K[E:\mathbb{Q}]d^2 \log(Nwd^2 \log N\nu + N \log d_E).$$

Since $\text{Frob}_{\nu'}$ does not act as a scalar on $\overline{M_\lambda}$, it does not act as a scalar on M_λ , and hence on M_{λ_0} either, and as ν is a prime of least norm with this property, we have an absolute and effective constant $c > 0$ with

$$N\nu \leq N\nu' \leq (e^{f(K)} \{N(wd^2 \log N\nu + \log d_E)\}^{n_K[E:\mathbb{Q}]d^2})^c.$$

Hence, we have proved that $N\nu$ is bounded by

$$\ll (e^{f(K)}(Nwd^2 \log d_E)^{n_K n_E d^2})^c (f(K) + n_K n_E d^2 \log(Nwd^2 \log d_E))^{c n_K n_E d^2 + 1}.$$

Here the implied constant is absolute and effective. Thus,

$$N\nu \leq c_1 B(Nwd^2 \log d_E, K, n_E, d)^c.$$

This contradicts our assumption and proves the lemma. ■

6 Proof of Theorem 1.4

By assumption, $\omega \in H_{\ell_0}^{2m}(\overline{A})$. Let M_{ℓ_0} be the $\mathbb{Q}_{\ell_0}[G_K]$ sub-module generated by ω inside $H_{\ell_0}^{2m}(\overline{A})$. Let λ_0 be a place of E lying over ℓ_0 . Let $M_{\lambda_0} := M_{\ell_0} \otimes_{\mathbb{Q}_{\ell_0}} E_{\lambda_0}$. Then by Theorem 3.2, M_{λ_0} is isomorphic (as $E_{\lambda_0}[G_K]$ module) to a sum of H_{J, λ_0} for certain subsets J of Ψ of size $2m$. Let us denote this set of subsets J of Ψ by \mathcal{J} . Thus,

$$(6.1) \quad M_{\lambda_0} = M_{\ell_0} \otimes_{\mathbb{Q}_{\ell_0}} E_{\lambda_0} = \bigoplus_{J \in \mathcal{J}} H_{J, \lambda_0}.$$

The right-hand side of (6.1) can be realised as the λ_0 component of a family of λ -adic representations, say $\{M_\lambda\}$, as follows. For any finite place λ of E , let

$$M_\lambda := \bigoplus_{J \in \mathcal{J}} H_{J, \lambda}.$$

By Corollary 3.3, $\{M_\lambda\}$ is a strictly compatible family of semi-simple λ -adic representations of G_K . It is easy to see from the definition that the conductor of this family is bounded by the conductor of the family $\{H_\lambda^{2m}\}$. Moreover, the conductor of H_λ^{2m} can be bounded in terms of m and the conductor N of A . In particular, we can get a bound depending on N and the dimension d of A that majorizes the conductor of all the $\{H_\lambda^{2m}\}$.

We have $n_E \leq (2d)!$ and the discriminant satisfies

$$\log d_E \leq (2d)! \log d_F.$$

Notice that $w = m \leq d$, and the dimension of the M_λ is equal to $\binom{2d}{2m} \leq 2^{2d}$. Thus, if we set

$$(6.2) \quad C(N, d, F, K) = c_1 B(2^{4d}(2d+1)!N \log d_F, K, (2d)!, 2^{2d})^c$$

where c, c_1 and B are as in Lemma 5.2, then applying Lemma 5.2 to $\{M_\lambda\}$, we get that G_K acts as scalars (i.e., acts by a one dimensional character) on $M_{\lambda_0} = \mathbb{Q}_{\ell_0}[G_K](\omega) \otimes_{\mathbb{Q}_{\ell_0}} E_{\lambda_0}$. This implies that $M_{\lambda_0} = \mathbb{Q}_{\ell_0} \cdot \omega \otimes_{\mathbb{Q}_{\ell_0}} E_{\lambda_0}$. Thus, $1 = \dim_{E_{\lambda_0}} M_{\lambda_0} = \dim_{\mathbb{Q}_{\ell_0}} M_{\ell_0}$, proving Theorem 1.4. ■

7 Proof of Theorem 1.9

Denote by $P(A_v, T)$ the characteristic polynomial of Frob_v . Writing

$$P(A_v, T) = \prod (1 - \alpha_i T) \in \mathbb{Z}[T]$$

we see that the α_i are algebraic of degree $\leq \deg P(A_v, T) = 2 \dim A_v = 2 \dim A$.

Moreover, for any $n \geq 1$, if $k_{v,n}$ denotes the extension of k_v of degree n ,

$$P(A_v/k_{v,n}, T) = \prod (1 - \alpha_i^n T).$$

Now,

$$\dim \mathcal{T}_\ell^k(\overline{A}_v, k_{v,n}) = \#\{I : \alpha_I^n = q^{kn}\},$$

where $\alpha_I = \prod_{\alpha_i \in I} \alpha_i$ and I runs over subsets of $\{\alpha_1, \dots, \alpha_{2d}\}$ of cardinality $2k$. The right-hand side is equal to

$$\#\{I : \alpha_I = q^k \zeta_n \text{ for some } \zeta_n \in \mu_n\}$$

But α_I is an algebraic number of degree $\leq b_{2k}(A) = \dim H_\ell^{2k}(\overline{A}) \leq \binom{2d}{2k}$. Hence if $\alpha_I = q^k \zeta_n$, then n is bounded. In other words, all Tate classes are defined over an extension of k_v of degree bounded independently of v . ■

8 Proof of Theorem 1.11

By definition, $\mathcal{T}_\ell^k(A)$ consists of cohomology classes $x \in H_\ell^{2k}(\overline{A})$ on which G_K acts by the character χ_ℓ^k , where χ_ℓ is the cyclotomic character of G_K acting on the Tate module $\mathbb{Z}_\ell(1)$. Note that we are assuming that K is sufficiently large so that all the Tate classes appear over K . By Theorems 3.1 and 3.2, we see that G_K acts on the 1-dimensional subspaces H_I by the Hecke character ψ_I . Here,

$$\psi_I = \prod_{j=1}^{2k} \psi_{i_j},$$

where I is the subset $\{i_1, \dots, i_{2k}\}$ of $\{1, \dots, 2d\}$. Thus,

$$(8.1) \quad \dim \mathcal{T}_\ell^k(A) = \#\{I \mid \psi_I = \chi_\ell^k\}.$$

Similarly, for a finite place v of K of good reduction for A ,

$$(8.2) \quad \dim \mathcal{T}_\ell^k(A_v) = \#\{I : \psi_I(\text{Frob}_v) = \zeta_n(\mathbb{N}v)^k\},$$

where ζ_n is some n -th root of unity where $n \leq \binom{2d}{2k}$ is bounded independently of v as proved in Theorem 1.9. Indeed, by Theorems 3.1 and 3.2, we see that Frob_v acts on the 1-dimensional vector subspaces H_I by multiplication by $\psi_I(\text{Frob}_v)$. On the other hand, by the above and by Theorem 1.9, $\mathcal{T}_\ell^k(A_v)$ consists precisely of those cohomology classes on which Frob_v acts by $\chi_\ell^k(\text{Frob}_v) = \zeta_n(\mathbb{N}v)^k$, and so (8.2) follows.

Thus, for all finite places v of good reduction, (8.1) and (8.2) imply:

$$S := \{I : \psi_I = \chi_\ell^k\} \subset S_v := \{I : \psi_I(\text{Frob}_v) = \zeta_n(\mathbb{N}v)^k\}.$$

Let

$$T := \{v \mid S \subsetneq S_v\}.$$

For any $v \in T$, there exists some $J \notin S$ (J depends on v) of cardinality $2k$ such that $\psi_J(\text{Frob}_v) \neq \zeta_n(\mathbb{N}v)^k$, where ζ_n is some n -th root of unity. We can write $T = \bigcup_{J \notin S} T_J$,

$$T_J := \{v \in T \mid \psi_J(\text{Frob}_v) = \zeta_n(\mathbb{N}v)^k\}.$$

We want to prove that T is of density 0. Suppose not. By the above, since there are only finitely many index sets J , there exists a $J_0 \notin S$ such that $\delta(T_{J_0}) > 0$. Hence, for all $v \in T_{J_0}$, $\psi_{J_0}^n(\text{Frob}_v) = (\mathbb{N}v)^{kn} = \chi_\ell^{kn}(\text{Frob}_v)$. Applying [9, Theorem 2, p. 163] to the characters $\psi_{J_0}^n$ and χ_ℓ^{kn} , we deduce that $\psi_{J_0}^n = \chi_\ell^{kn} \chi_1$, where χ_1 is a character of finite order. Hence $\psi_{J_0}^n = \chi_\ell^{kn}$ when restricted to $G_L := \text{Gal}(\overline{K}/L)$, where L is the fixed field cut out by $\text{Ker}(\chi_1)$. Thus, $\psi := \psi_{J_0}^n \cdot \chi_\ell^{-kn}$ is a character of G_L of order n . Thus $\psi_{J_0} = \chi_\ell^k$ when restricted to $\text{Gal}(\overline{K}/L_\psi)$, where L_ψ is the number field cut out by $\text{Ker}(\psi)$. This implies that J_0 contributes to a new Tate cycle on A . However, this is a contradiction, since by assumption all the Tate cycles are defined over K and $J_0 \notin S$. This proves that T has density 0, which proves the result. ■
